By Andrew Warner LONDON (Reuters) - Scientists are trying to discover the origins of the unexplained energy emitted by the Earth, a vast battery of mysterious pulsating power that could provide a new and clean source of electricity, they said on Wednesday. They are listening for signals from across the universe that tell them something about its origin and how much of the power was given off billions of years ago. "If we learn how to tap this source, we will be able to create clean power with almost no harmful emissions," said physicist Alex Levashev, who is working with other scientists on a project called the Large Aperture Experiment to Detect a Neutrino of Dark Origin (LADON) at the Karlsruhe Institute of Technology in Germany. Neutrinos are particles with almost no mass, they interact only with other matter and even though they were the first particle predicted by Albert Einstein's theory of relativity, they were not found until the 1930s. To date no-one knows how many neutrinos exist in the universe. A recent scientific theory suggests there are about a hundred billion billion trillion trillion neutrinos in every cubic centimeter of space, but no-one has ever managed to detect them. LADON was launched last July aboard a balloon that rose to 102,000 feet (31,000 meters) above the Earth, where it is still floating above the Atlantic Ocean between Brazil and Africa. It detected neutrinos that had travelled close to the speed of light from 2d92ce491b
