Inactivation of one X chromosome during female mammalian development has been extensively studied, but the mechanisms leading to X chromosome inactivation remain poorly understood. To test X chromosome inactivation in vivo, we constructed a mouse strain in which the X chromosome could be inactivated on a temporary basis by Cre recombinase. A mouse gene encoding a truncated form of the murine coagulation protein factor X (FX) was deleted in embryonic stem cells that contained the Xist gene by flanking its translation initiation site with two loxP sites. The transgene encoding Cre recombinase was introduced into these cells to initiate X chromosome inactivation. As a consequence of the Cre recombinase-induced truncation, two X chromosomes were genetically modified in embryonic stem cell clones, allowing them to remain viable through differentiation. All of the cloned mice became hemizygous for FX and were phenotypically normal. At the embryonic day 15.5, when expression of the Xist gene is initiated, only one of the X chromosomes is expressed and is thereby inactivated. Importantly, inactivation of the X chromosome in our mice is not permanent, since inactivation is reverted in a subset of female embryos. These mice constitute a novel model system for the transient inactivation of the X chromosome during mammalian development.
