Minecraft Texture Pack - Instructions. would expect the majority of the filaments to be below our detection limit, however, at this point we have no knowledge of their locations. Massive filaments ----- Observations of massive filament strands in the southern Milky Way have been previously reported by Reid et al. (2004). The typical orientation of these structures implies that they are associated with the spiral arms of the Galaxy. Further observations are needed to confirm this hypothesis. The current filament population is significantly more massive than that of Reid et al. (2004), however, there is not a one-to-one correspondence between massive filaments and the radial density distribution of the dust. The single filament analysed by Reid et al. (2004) had a mass of $600 M_{\odot}$, based on continuum millimetre-wave emission observed with the IRAM 30m telescope. Our map has a mass of $3.5 \times 10^6 M_{\odot}$ (see Figure \[fig:filaments\]).

Although this mass estimate may be affected by thermal noise, the fact that our maximum filament length is over 600pc suggests that it is likely to be considerably less than the typical filament length of 1-2kpc. This suggests that a fraction of the filament population is significantly less massive than our estimate. The implication is that these objects may be significantly unstable, implying that filament fragmentation must be a common phenomenon. As the filaments fragment their component substructure may follow a somewhat flattened profile. The model for filament fragmentation presented by McKee (1987), for example, predicts that an initially cylindrical gravitational flux tube undergoes a hydrodynamic instability, which causes the gas to deviate from the rigid cylindrical geometry. The reduced inertia of this mass stream enhances the development of Kelvin-Helmholtz instabilities, which cause the gas to fragment into layers which are subsequently further unstable. Hence, we could envisage an initial phase of filament fragment formation in 0298e982ba
