# Color Palettes and Color Management Photoshop, like most image editors, supports the ability to change the color of an image at the pixel level, which is handy when you need to keep an image consistent or create original new images that use different hues of the same color spectrum. However, color management is best thought of as a much more complex function than just adjusting color. Essentially, it's the procedure that controls how the hardware, the software, and the applications in your computer convert the data coming from the camera to the output you see in the final image on your monitor or the print you make. To ensure that color management works correctly, Photoshop and all your image software can tell you the color profile of the display (usually selected by default) and the hardware that you have on the computer. The color profile is a mathematical formula that identifies the color space the monitor hardware is working in, and it's typically provided by the manufacturer. When you're working with data that's not in the same color space as the device that's displaying the image, colors can look really strange and sometimes make images look like they're not really the colors they should be. To ensure that colors look accurate, you need to use a color profile that matches the range of colors and end up with an image that's calibrated in the correct color space. To explain the color management process in more detail, Adobe provides a really helpful DVD tutorial that teaches the basics of color management in Photoshop CS5: Digital Classroom: Retouching & Color Management. Photoshop CS4 provides a Color Management system that offers two different ways to set up your color space: using "Perceptual Color" or using a profile. Photoshop CS4 provides a better Color Management system than Photoshop CS2, which didn't offer the Color Management tools that are in current versions of Photoshop. Photoshop CS5 provides a Color Management tool set that's really intuitive: it automatically detects the profile in the file and enables you to choose one from a list of profiles that are stored in the swatches palette. To access the Color Management options in Photoshop, choose Edit Color Management Edit Color Management Settings. Figure 2-6 shows the Color Management options in Photoshop CS5. In the Swatches palette, all the different profiles

As a general rule, menopause begins for many women as the result of declining estrogen levels in a woman's body. Because of the numerous and varied health problems associated with menopause, women look for ways to manage and regulate their health. One way that many women manage their menopausal health is through the use of hormone replacement therapy (HRT). HRT is particularly beneficial for women who have already lost the ability to produce estrogen in their own bodies. HRT can provide many benefits to women who are menopausal, even if the menopause is due to an extremely high dose of estrogen in their system. HRT begins with the administration of estrogen-based hormones. It is believed that estrogen reduces the risks of heart disease, osteoporosis, and a variety of other degenerative conditions. Hormone replacement therapy is a process in which a woman's body is treated with estrogen-based hormones. Although various estrogen-based medications are available, estrogen replacement therapy is most often discussed in terms of two hormonal options: estrogen alone and estrogen combined with progesterin. Estrogen replacement therapy is extremely effective in its treatments for the health and well-being of postmenopausal women. Various studies have shown that estrogen replacement therapy can help prevent osteoporosis and heart disease. In the process of administering HRT to a patient, it is important to monitor and control certain important health markers, such as lipid levels. For example, because of their effect on lipids, various hormones can cause or exacerbate a variety of health problems associated with elevated or reduced lipid levels. Therefore, it is important to maintain patients' cholesterol at normal levels. Certain lipoproteins in the blood, including the LDL cholesterol level, are associated with a high risk of heart disease. Various hormones can affect the lipoproteins of patients. For instance, because progesterone increases cholesterol levels, high doses of progesterone may lead to elevations of cholesterol levels. Estrogen may also contribute to elevations in LDL cholesterol. Thus, certain hormones can contribute to increases in cholesterol levels. One hormone that has been linked to increased lipid levels is cortisone. Cortisone is an anti-inflammatory steroid hormone produced by the adrenal glands. Although cortisone is commonly used to treat inflammation associated with conditions such as arthritis, asthma, lupus, or colitis, it also causes the body to have more cholesterol. In the body, cortisone enters the liver where it affects a variety of important liver

LIMK1, an interacting protein of myosin light chain kinase, regulates cell migration and metastasis of hepatocellular carcinoma. LIM kinase 1 (LIMK1) is a protein kinase belonging to the LIM family and involved in the regulation of cell polarity, motility and adhesion. Recent studies have demonstrated that LIMK1 is overexpressed in several types of malignancies and LIMK1 is involved in cell migration. The present study aimed to investigate the role of LIMK1 in hepatocellular carcinoma (HCC) metastasis. LIMK1 mRNA and protein expressions were detected in HCC cell lines and clinical HCC specimens, respectively. HCC cell migration was examined in LIMK1-silenced Huh7 and HepG2 cells in vitro and in vivo using transwell assays
